ABSTRACT

A method of monitoring browser interactions with a server arrangement includes: capturing information regarding requests and corresponding responses; identifying sessions, each session including requests received at the server arrangement and corresponding responses; assigning a session identification (SessionID) for each identified session; recording in a database the SessionID, the content of each respective request in the session, the content of each corresponding response, and a chronological order of the requests; and re-creating selected pages representative of a particular browser's interactions and identifying browsing patterns.
